COMPUTER PROGRAMMING · PRACTICE

Sort Three Numbers

DESCRIPTION

You are given three integers x, y, and z. Print them in ascending order (smallest first). Some of the numbers may be negative, and some of them may be equal.

This is a pointer exercise, so the ordering must be done by a helper function that works on addresses.

REQUIRED FUNCTION

Your program must define the following function:

```
void order(int *a, int *b)
```

- It looks at the two integers that `a` and `b` point to. If `*a > *b`, it swaps the two values; otherwise it changes nothing. After the call, `*a <= *b` always holds.
- It must read and change the values through `*a` and `*b`. It returns nothing.
- In `main`, read x, y, and z, then call the function three times, in exactly this order, passing the **addresses** of the variables with `&`:

```
order(&x, &y);
order(&y, &z);
order(&x, &y);
```

(After the first two calls, z holds the largest value. The third call puts x and y in order.)

Finally, print x, y, and z.

INPUT FORMAT

The input contains one line with three integers x, y, and z, separated by single spaces.

$-10^9 \le x, y, z \le 10^9$. The values may be negative, zero, or equal to each other.

OUTPUT FORMAT

Print the three integers in ascending order on one line, separated by single spaces, followed by a newline. Do not print a space after the last number.

SAMPLE

Sample 1 Input

```
5 9 -4
```

Sample 1 Output

```
-4 5 9
```
